Hearing loss is a growing problem...

Hearing Loss is the **3rd** most common health problem among older adults in the US.

— “ —

There is no such thing as insignificant hearing loss. Any type and degree of hearing loss will have a substantial impact on many aspects of living.

— ” —

Approximately **1 in 8** children ages 6-19 have noise-induced hearing loss.

1.1 billion people are at risk for hearing loss due to unsafe personal use of portable music devices.*

Approximately **30 Million** workers are exposed to noise levels on the job.

Hearing tests can help detect hearing loss early, which can be critical for successful treatment. An experienced audiologist will determine your plan of care based on the degree of loss you experience and prevent the chances of further damage to the auditory system. Regular screenings are an important tool for maintaining good hearing health.

*Limit your use of portable devices and keep the volume level at the half-way point or under. If you have to remove your headphones in order to hear someone speaking from an arm length away, it's probably unsafe.

Have you heard?

Your hearing affects your whole body health.

COGNITIVE DECLINE

Those with hearing loss experience a 30-40% greater decline in thinking abilities and a higher risk of dementia.

SAFETY/BALANCE

People with mild hearing loss are 3 times more likely to have a history of falling. Every additional 10 decibels of hearing loss increases the chances of falling by 1.4 times.

HYPERTENSION

There is a significant association between high blood pressure and hearing loss. Hypertension can be an accelerating factor of hearing loss in older adults.

OBESITY

Higher body mass index (BMI) and a larger waist circumference are associated with an increased risk of hearing loss in women.

OSTEOPOROSIS

A study linked osteoporosis and hearing loss, theorizing that demineralization of the three middle ear bones may contribute to conductive hearing impairment.

ISOLATION

Adults 50 years and older with untreated hearing loss are more likely to report depression, anxiety, anger, frustration, emotional instability, and paranoia than those with hearing aids.

TINNITUS

Tinnitus affects 1 in 5 people and 90% of people with tinnitus also have hearing loss.

Tinnitus can be caused by hearing loss, an ear injury, or a circulatory system disorder.

DEPRESSION

Uncorrected hearing loss gives rise to a poorer quality of life, isolation, and reduced social activity leading to depression.

HEART HEALTH

The inner ear is extremely sensitive to blood flow. Studies show that a healthy cardiovascular system - a person's heart, arteries, and veins, positively affects hearing. Inadequate blood flow and trauma to the blood vessels of the inner ear contribute to hearing loss.

SMOKING

Current smokers have a 70% higher risk of hearing loss than nonsmokers.

DIABETES

Hearing loss is twice as common in people with diabetes compared to those without. Adults whose blood glucose is higher than normal but not high enough for a diabetes diagnosis have a 30% higher rate of hearing loss compared to those with normal.

OTOTOXICITY

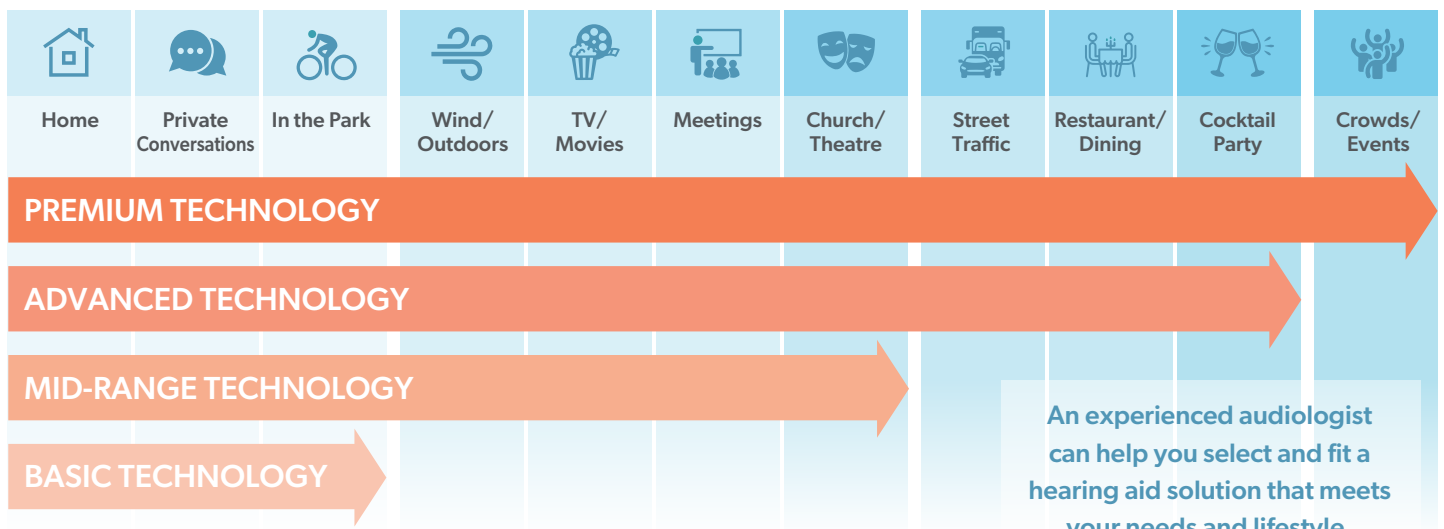

There are more than 200 medications on the market today that are known to cause hearing loss. The list of known ototoxic drugs (toxic to the ears) includes aspirin, quinine, water pills, certain antibiotics, some anticancer drugs, some anesthetics, environmental chemicals like carbon monoxide, hexane, and mercury.
